Abstract

Background: A project aimed at studying the frequency of dementia and depression in the catchment area of the Health Centre of Chrisoupolis (HCCh), Northern Greece, was carried out. This paper reports the association between AD and anemia among the elderly participants in this Greek study.

Methods: Eligible participants were people 65 years or over who were (a) living in the Elderly People’s Home (all 48 subjects included); (b) visiting the Open Center for Elderly People during a 20 workday period (75 subjects) and (c) visiting the HCCh for routine medical care. The Mini Mental State Examination (MMSE) was used in assessing the cognitive capacity of the participants. Blood was drawn for serum hematocrit, vitamin B12 and folate determination.

Results: The prevalence proportions of possible cognitive impairment among anemic and non-anemic males were 55.6% and 34.4%, respectively ($X^2 = 5.8$, d.f. = 1, $p = 0.016$). The corresponding proportions in females were 47.5% and 40.1% ($X^2 = 1.1$, d.f. = 1, $p = 0.305$). Using logistic regression analysis, age-group ($\geq 80$ yrs), type of Institute, vitamin B12 and anemia had significant independent associations with possible cognitive impairment.

Conclusions: Anemia is a frequent finding in elderly and it may be a risk factor for dementia, but the extent of the associated deterioration of cognitive impairment or the relation with AD is not known. GPs should be aware of this coexistence and recommend for screening, assaying and treating elderly people.

Background

Alzheimer's disease (AD) and other neurodegenerative diseases affect large parts of the population worldwide and they constitute a serious public health problem for the aging European population [1–4]. General Practitioners seem to be able to diagnose early cognitive impairments, after training, among their elderly patients [5,6]. Identifying reversible and avoidable cognitive impairments seems to be also a challenge for future General Practitioners (GPs). There are many controversies regarding various associated factors, which can affect the incidence and progress of Alzheimer's disease (AD) [7,8].
Among these factors, vitamin B12 deficiency and folate status deterioration have been extensively discussed. Although some studies reported that anemia might be a risk factor for AD in the elderly [9–12] this subject is still debated in the literature.

A project with the aim of studying the frequency of dementia and depression among the elderly people in the catchment area of the Chrisoupolis Health Center (HCCh) in Northern Greece has been carried out during the past few years. A high prevalence of cognitive impairment has recently been reported in this area [13]. Thus, it was interesting to study and discuss the laboratory findings of the eligible subjects together with their mental status ability. This paper reports the association between cognitive impairment and anemia among the elderly participants in this Greek study.

**Patients and Methods**

**Setting**
This cross-sectional study was carried out at the catchment area of the (HCCh) in Northern Greece, which comprises 22,000 inhabitants.

**Participants**
Eligible participants were people 65 years or over who were (a) living in the Elderly People’s Home (all 48 subjects included); (b) visiting the Open Center for Elderly People during a 20 workday period (75 subjects) and (c) visiting the HCCh for routine medical care. The latter group comprised of 413 subjects, which were randomly selected among the elderly people visiting one of the two outpatient clinics of the health center for the same period of time. Thus the total number of participants was 536, 245 males and 291 females. Baseline data of the studied population were presented in Table 1.

The study has been approved by the Scientific and Ethical Committee of the General Hospital of Kavala, Greece.

**Tests**
The Greek validated version of Mini Mental State Examination test (MMSE) was used [14]. For diagnostic classification of cognitive and mood disorders the criteria of ICD-10 were applied [15]. Any subject with an MMSE score of 24 or less was included in the possible cognitive impairment group for analyses.

Blood (10 cc) was drawn for mean hematocrit (HCT), vitamin B12 (Vit.B12) and serum folate concentrations and was assayed in the lab of the HCCh. HCT was defined with microHt method. Normal values were considered when HCT was ≥38% for males and ≥36% for females. Vit.B12 was defined with the Elisa method in the micro Merieux analyzer. Normal values for Vit.B12 were considered those higher or equal to 145 pg/mL. Folate was determined with I CIA method (Ion Capture Immune Assay), in Imx automatic analyzer. Normal values for folate were considered those higher or equal to 1.8 ng/mL. Quality control is applied at this lab on a regular basis.

| Table 1: Demographic and backgrounds characteristics of the studied population |
|-----------------------------|-----------------------------|-----------------------------|-----------------------------|-----------------------------|
| Variable                    | Elderly Home N (%)          | Open Centre for Elderly People N (%) | Chrissoupolis Health Centre N (%) | Total N (%)                |
| Age 65–74 years             | -                           | 73 (27.1)                   | 196 (72.9)                   | 269                         |
| 75–84                       | 32 (17.1)                   | 2 (1.1)                     | 153 (81.8)                   | 187                         |
| 85+                         | 16 (20.0)                   | -                           | 64 (80.0)                    | 80                          |
| Total                       | 48 (9.0)                    | 75 (14.0)                   | 413 (77.1)                   | 536                         |
| Sex Males                   | 19 (7.75)                   | 72 (29.4)                   | 154 (62.9)                   | 245                         |
| Females                     | 29 (10.0)                   | 28 (9.6)                    | 234 (80.5)                   | 291                         |
| Marital status              | 48 (34.04)                  | 4 (2.8)                     | 89 (63.1)                    | 141                         |
| Married                     | -                           | 71 (18.0)                   | 324 (82.0)                   | 395                         |
| Widowed                      | 17 (13.4)                   | 9 (7.1)                     | 101 (79.5)                   | 127                         |
| Education level <6 years education | 11 (3.5)                   | 32 (10.2)                   | 270 (86.3)                   | 313                         |
| 6–12 years education        | 20 (20.8)                   | 34 (35.4)                   | 42 (43.7)                    | 96                          |
All statistical analyses were carried out using SPSS for Windows (Release 10.0). The associations between categorical variables, such as different subject groups and prevalence of disorders, were tested by means of Pearson's chi square-test or Fisher's test where was appropriate. To show the strength of the association, p-values are shown in the text [16]. Comparisons of mean values between groups were made by Student's t-test or analysis of variance. The independent influence of all potential factors in identifying the presence of cognitive impairment was studied by means of unconditional logistic regression analysis [17].

**Results**

**Anemia and cognitive impairment**

Ninety-five (17.7%) out of the 536 participants were found to be anemic. Of those, 47 scored higher than 24 in the MMSE and 48 lower or equal to 24 (possibly cognitive impairment) (Table 2). The association between anemia and possible cognitive impairment was statistically significant ($X^2 = 5.6$, d.f. = 1, $p = 0.018$). A separate analysis by gender revealed that this association was true only for males and not for females. In fact, in males the prevalence proportions of possible cognitive impairment among anemic and non-anemic subjects were 55.6% and 34.4%, respectively ($X^2 = 5.8$, d.f. = 1, $p = 0.016$). The corresponding proportions in females were 47.5% and 40.1% ($X^2 = 1.1$, d.f. = 1, $p = 0.305$).

**Vitamin B12 and cognitive impairment**

The analysis of blood sample of the participants indicated an abnormal value of Vit.B12 in 56 (10.4%) subjects. Of those, 25 subjects scored as normal in the cognitive test and 31 were assessed as possibly cognitive impaired. The prevalence proportions of possible cognitive impairment among male participants with normal and abnormal value of Vit.B12 were significantly different, 34.8% and 62.5%, respectively ($X^2 = 7.1$, d.f. = 1, $p = 0.008$). The corresponding proportions in females were not significantly different, 40.5% and 50.0% ($X^2 = 1.0$, d.f. = 1, $p = 0.306$).

**Folate and cognitive impairment**

Fifteen (2.7%) subjects (7 with a MMSE lower or equal to 24) were found to have an abnormal value of folic acid. The prevalence proportions of possible cognitive impairment among participants with normal or abnormal value of folic acid were 39.5% and 46.7%, respectively. The association between folic acid and possible cognitive impairment was not significant ($X^2 = 0.3$, d.f. = 1, $p = 0.578$).

**Differences among the three institutions**

A two-way analysis of variance, by MMSE classification and institution, revealed significant differences between the three institutions in HCT and folate ($F = 4.2$, d.f. = 2 and 530, $p = 0.016$ and $F = 4.9$, d.f. = 2 and 530, $p = 0.008$, respectively), and marked, but not significant differences in Vit.B$_{12}$ ($F = 2.7$, d.f. = 2 and 530, $p = 0.068$). The results depicted in Table 3, show that subjects living in the Old People's Home (OPH), had the lowest value of HCT and Vit.B$_{12}$, while those participating in the Open Centre for the Elderly people (OCE) had the lowest value in folate. There were similar results with respect to differences between the two MMSE categories: participants with possible cognitive impairment had lower values in HCT, Vit.B$_{12}$ and folate, than those with normal MMSE score. The results in Table 3, show that the above results for the MMSE categories were not consistent across all three institutions, in particular those for Vit.B$_{12}$ and folate, where a reverse difference was observed in subjects from the OPH. This MMSE classification by institution interaction was significant only for folate ($F = 9.1$, d.f. = 2 and 530, $p < 0.001$).
Logistic regression analysis

The results of the logistic regression analysis (backward, unconditional maximum likelihood) are illustrated in Table 4. Age-group (≥ 80 yrs), type of institution, anemia, Vit.B\textsubscript{12} and folate concentrations had marked or significant independent influences on the presence of cognitive impairment, as indicated by MMSE score less than the cutoff point of ≤ 24. Table 4, shows also the odds – ratios and 95% CI for each of the above factors; it can be seen that the risk of cognitive impairment (as measured by the odds-ratio) for age greater than 80 years, OPH residence and abnormal value of HCT, Vit.B\textsubscript{12} is significantly higher than one.

Discussion

It is widely accepted that anemia is a common health problem among elderly people, and cobalamin deficiency increases with advancing age. Although there are several studies which report an association between cobalamin deficiency and cognitive impairment [18–21], more studies are required to determine whether there is a specific profile of cognitive impairments typical of Vit.B\textsubscript{12} deficiency. It is also widely accepted that cobalamin deficiency may result in a variety of atypical symptoms and hematological changes typical of megaloblastic anemia are frequently absent in the majority of patients with mental disorders [22].

Our study indicated an association between cognitive impairment and anemia, but causation cannot be as-
sessed on the basis of the results of this cross-sectional study. Why this association exists needs further discussion. The impact which the changes on olfactory function and taste associated with AD may have on dietary intake, nutritional status and the haematologic factors is not examined in this study. The possible contribution of the concomitant diseases on the causation of anemia should not be ignored, when the results are interpreted. The present study is based on people who have visited the Health Centre and other older people who live at the community setting. This situation reflects the current figure of the real context in which the GPs are invited to work. Anemia was also based on the HCT findings, but both HCT and the blood Hb concentration remain the best available indirect indicators [23,24]. The validity and reliability of the used laboratory methods is an important issue as it can affect the study results. However the lab of the HCCh was using quality controls and all the blood tests were administered by the same assistant. The use of MMSE as a screening tool has also been discussed widely in the literature [25,26]. Even the MMSE’s specificity and sensitivity can be affected by factors such as sex, education level, age [27] this tool remains to be a simple screening tool at GP’s disposal for cognitive impairment and cannot be used to make even tentative psychiatric diagnoses [26,27].

Despite these limitations, our study adds to the existing literature. This study also reveals that people, who are living in Old People’s Homes, were recognized at a specific risk and it is also in accordance with other reports [28,29]. The greater risk of male subjects having cognitive impairment when they are anemic in comparison with females has been reported in another study [9].

This Greek study may have some serious implications on the GPs attitude and practices when they identify elderly cognitive impaired subjects; specifically, they could recommend them a hematological investigation including HCT, CBC, Vit.B12 and folate acid levels. The initiation of a adequate treatment with Vit.B12 and/or folate when laboratory indications exist, seems to be an effective strategy in General Practice and this treatment is recommended, even in cases with a normal score with MMSE. Some authorities recommend that serum B12 screening should be initially performed to all elderly patients, with further testing in those with a Vit.B12 level of less than 350 pg/mL (260 pmol/L) [20]. Seeking the effectiveness of different screening strategies, clinicians need to use their own judgment to decide how to identify Vit.B12 deficiency before it leads to anemia or neurologic disease.

Conclusions
Anemia seems to be a risk factor for cognitive impairment. There are also many questions whether Vit.B12 and folate deficiency work as risk factors on the onset of dementia and whether the appearance of dementia can be avoided by a supplemented treatment. Until definitive clarifying of those questions GPs should be warranted to screening, assaying, and treating elderly people.
